

## A little program transformation

We consider two programs  $p$  and  $q$ , sharing the variables  $x.p$ ,  $x.q$ , and  $h$ . The initial state satisfies  $\neg x.p \wedge \neg x.q \wedge (h \neq p \vee h \neq q)$ . Program  $p$  is a cyclic program with body

```

x.p, h := true, p
; if  $\neg x.q \rightarrow$  skip
   $\square$   $h \neq p \rightarrow$  skip
fi
; CS.p
; x.p := false.

```

Each line of code is (considered to be) atomic. Program  $q$  is Program  $p$  with  $p$  and  $q$  interchanged.

Next, we deem to have shown that the above multiprogram is a correct mutual exclusion algorithm as far as its safety is concerned. We also deem to have shown that safety is preserved by "strengthening a guard". We will use the latter to transform the above mutual exclusion algorithm into another one in which the atomic multiple assignment no longer occurs.

To that end we introduce a fresh shared variable  $y$  that will take over the rôle of  $x$ . Because safety is preserved by strengthening a guard, we require  $y$  to satisfy  $\neg y \Rightarrow \neg x$ , or -- equivalently:  $x \Rightarrow y$  --. This leaves us no

choice on the relative order of the assignments  
 $x := \text{true}$  and  $y := \text{true}$ . For program  $p$   
 we obtain

```

    y.p := true
  ; x.p, h := true, p
  ; if  $\neg y.p \rightarrow \text{skip}$ 
    ||  $h \neq p \rightarrow \text{skip}$ 
    fi
  ; CS.p
  ; y.p, x.p := false, false ,
  
```

from which thought variable  $x$  can now be removed

\*

From experience we know that the requirement to use fine-grained atomic statements can considerably complicate the design and discussion of multiprograms. From the above example we can learn that perhaps sometimes the concern about the granularity is a completely separable one.
